Geometry Info Sheet #28

Theorems for Special Quadrilaterals

Theorems

If <u>both pairs</u> of <u>opposite sides</u> of a quadrilateral are <u>congruent</u>, then the quadrilateral is a **parallelogram**.

If <u>both pairs</u> of <u>opposite angles</u> of a quadrilateral are <u>congruent</u>, then the quadrilateral is a **parallelogram**.

If <u>one pair</u> of <u>opposite sides</u> of a quadrilateral is <u>congruent and parallel</u>, then the quadrilateral is a **parallelogram**.

If the <u>diagonals</u> of a quadrilateral <u>bisect each other</u>, then the quadrilateral is a **parallelogram**.

If <u>one pair</u> of <u>adjacent sides</u> of a parallelogram is <u>congruent</u>, then the parallelogram is a **rhombus**.

If the <u>diagonals</u> of a parallelogram <u>bisect the angles</u> of the parallelogram, then the parallelogram is a **rhombus**.

If the <u>diagonals</u> of a parallelogram are <u>perpendicular</u>, then the parallelogram is a **rhombus**.

If <u>one angle</u> of a parallelogram is a <u>right angle</u>, then the parallelogram is a **rectangle**.

If the <u>diagonals</u> of a parallelogram are <u>congruent</u>, then the parallelogram is a rectangle. This theorem is sometimes called the <u>House Builder Theorem</u>.

If a trapezoid has a pair of congruent base angles, then the trapezoid is isosceles.
