Geometry Info Sheet #46

Areas of Rhombuses, Kites, and Regular Polygons

Definitions

Polygon: A two-dimensional closed plane figure made up of at least three straight line segments (no curves) such that each segment intersects exactly two other segments; the line segments are the <u>sides</u> of the polygon, and the common endpoints of the segments are the <u>vertices</u>

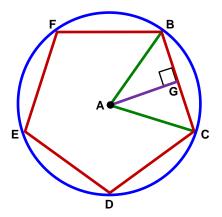

A <u>diagonal</u> of a polygon is a segment that joins two non-adjacent vertices.

Regular Polygon: A polygon in which all of the sides are congruent and all of the angles are congruent

A <u>central angle</u> of a regular polygon is an angle whose vertex is the center of the polygon and whose sides pass through two consecutive vertices of the polygon.

Apothem: A line segment from the center of a regular polygon to the midpoint of any side, forming a right angle

The <u>center</u> and <u>radius</u> of a regular polygon are the center and radius of the polygon's circumscribed circle.

Circle A is circumscribed about the regular polygon **BCDEF**.

Center:	А
Radii:	\overline{AB} and \overline{AC}
Apothem:	ĀG
Central Angle:	∠BAC

Formulas

The <u>area</u> A of a <u>rhombus</u> or a <u>kite</u> with diagonals d_1 and d_2 is given by: $A = \frac{1}{2}d_1d_2$ The <u>area</u> A of a <u>regular polygon</u> with apothem a and perimeter p is given by: $A = \frac{1}{2}ap$ The measure of a <u>central angle</u> of a <u>regular polygon</u> with n sides is: $\frac{360^{\circ}}{n}$
